

# Immunotherapy

Department of Immunology  
2nd Medical School  
Charles University, Prague

December 2008

# Interventions with impact on the immune system

## ◆ immunomodulation

- it is not clearly possible to distinguish stimulation from suppression

◆ overreacting IS	➡	immunosuppression
◆ insufficient IS	➡	immunostimulation

◆ antigen specific

◆ antigen non-specific

# Legend

- ◆ effect specificity
- ◆ speed of effect
- ◆ frequency of clinical usage

# Effect of glukocorticosteroids

- ◆ interaction with gene transcription
- ◆ reduction of transcription of genes for pro-inflammatory cytokines
- ◆ limiting activity and presence of immunocompetent cells in the inflammed region (effect on endothelium, decrease of chemotaxis)
- ◆ influence of number and function of immunocompetent cells
- ◆ main usage:
  - autoimmunity, GvHD prevention and malignancy

# Effect of glukocorticosteroids

	Effect	Mechanism
Cellular transport	↑ neutrophils in circulation	release from BM but limited access into the tissues
	↓ monocytes in circulation	
	↓ lymphocytes (mainly CD4+)	apoptosis of CD4+ T cells sequestration within BM
Cellular function	↓ activity of macrophages	↓ maturation of M0 from monocytes
	↓ production of proinflammatory cytokines (IL-1, 6, TNF-alfa)	
	↓ chemotaxis	
	↓ baktericidia	
	↓ T cell activation	↓ transcription of genes for IL-1,2,3,4,6, IFN-gamma
	↓ function of endothelium	↓ expression of adhesive molecules
	↓ function of NK cells	↓ actioivity of NO synthese
Inflammation	↓ prostaglandins synthesis	↓ inhibition fof phospholipase A2 and cyclooxygenase

# Adverse effects of glucocorticosteroids

depression, mood changes

skin atrophy

cataract

acne

hirsutism

proximal myopathy

hypertension

gastric ulcer

diabetes mellitus

suppression of adrenal glands

aseptic necrosis

osteoporosis

impaired wound healing

Cushingoid habitus

increased infection rate

decreased growth dynamics

# Effects of NSAID on IS

- ◆ inhibition of cyclooxygenase (COX-1,2) → ↓ prostaglandin E2
  - ◆ ↑ late sensitivity reaction
  - ◆ ↑ rejection of skin grafts as well as tumours in experimental animals
  - ◆ ↓ serum concentration of RF IgM in patients with RA
- 
- ◆ main usage: analgesics, antipyretics
  - ◆ one of the most spread drugs in the world
    - : acetylsalicylic acid, ibuprofen, celecoxib (Vioxx, Celebrex, GIT bleeding, myocardial infarction...)

# Antihistaminics

## ◆ generation I

- dithiaden

## ◆ generation II

- cetirizin, loratadin (Zodac, Zyrtec, Claritine...)
- decreased transport through hemato-encephalic barrier

## ◆ generation II-III

- antihistaminics with immunomodulatory effect – decrease of adhesive molecules, anti-inflammatory effect
- desloratadin, levocetirizin (Xyzal, Alerius)

# Antihistaminics

# Antileukotriens

◆ inhibition of leukotrien production  
(or its receptors)

- zafirlukast, montelukast (Singulair)

◆ usage:

- mild form of bronchial asthma
- activity-induced asthma
- ACP-sensitive asthma

# Antileukotriens

# Immunosuppressive drugs

## ◆ a) immunomodulatory drugs

- antagonists of folic acid - methotrexate
- purin analogs – azathioprin, mykofenolate mofetil
- alkylating agents - cyklophosphamid
- sulfasalazin
- antimalarics

## ◆ b) drugs binding to immunofilins

- cyklosporin A
- tacrolimus (FK 506), sirolimus

## ◆ c) anti-T, anti-B

- anti -T:
  - ◆ anti-thymocytic globulin
  - ◆ monoclonal antibodies against CD3, CD4, CD52, CD25
  - ◆ organ transplantation– rejection, GvHD
- anti-B
  - ◆ anti-CD20 (Rituximab)
  - ◆ lymphoma, autoimmune disease

# Purine analogs

## ◆ Azathioprine (Imuran)

- inhibition of synthesis DNA
- metabolites are active (after metabolization in liver)
- effects are seen after several weeks
- bone marrow toxicity (granulocytopenia, trombocytopenia)
- homozygotic deficiency of TPMT (thiopurine-methyl transferase) – life-threatening bone marrow aplasia

## ◆ Mycophenolate mofetil (CellCept)

- inhibition of inosine-monophosphate dehydrogenase = key enzyme in de novo synthesis of purines for T and B cells

# Alkylating agents

- ◆ interference with DNA duplication in pre-mitotic phase
- ◆ DNA reparation after alkylation is different in particular tissues

## Cyclophosphamide

- metabolites are active (after metabolization in liver)
- clear mechanism of action is not known
- reduced response on antigen stimulation
- after discontinuation return to normal takes weeks and months
- long-term application connected with urinary bladder carcinoma

## Chlorambucil

- directly affects B cells
- B-cell tumours, leukaemias

# Agents binding immunophilins

## Cyclosporine A

- ◆ binds to intracellular receptors – cyclophilin – calcineurin
- ◆ inhibition of translocation of transcription factors into nucleus – inhibition of calcium-dependent processes
- ◆ main effect is decreased production of IL-2 (affects CD4+ dependent processes)
- ◆ main usage
  - prolongs survival of grafts after transplantation
  - in autoimmune diseases where CD4+ play major role- psoriasis, uveitis, severe RA, AD
- ◆ effect seen after in 2-12 weeks, sometimes rebound phenomenon
- ◆ nephrotoxicity, hypertension, hepatotoxicity, gingival hyperplasia, tremor, hirsutism, lymphoma

## FK506 (tacrolimus)

- ◆ binds to intracellular protein, similar mechanism as CyA, but 10-100x more potent
- ◆ higher nephrotoxicity than in CyA

## Rapamycine (Sirolimus)

- ◆ similar to FK506, transcription of cytokines not influenced
- ◆ T-hb inhibition of proliferation after stimulation by IL-2, 4

# Anti-cytokine therapy

## Monoclonal antibodies against TNF - alpha

- ◆ infliximab (Remicade) - chimeric
- ◆ adalimumab (Humira) - humanized
- ◆ etanercept (Enbrel) – humanized, receptor inhibitor
- ◆ anti-dsDNA Ab induction, increased incidence of tuberculosis
- ◆ RA, JCA, Crohn, Bechtěrev

## Inhibition of IL-1 - Interleukin1-RA = Anakinra (Kineret)

- ◆ frequent usage, extremely expensive

# Immunostimulation

- ◆ bacterial lysates – non-specific activation of macrophages
  - Bronchovaxom, Ribomunyl, Luivac etc.
- ◆ chemical immunostimulation
  - not widely used
  - Isoprinosine, Levamisol
- ◆ vaccination

# Immunoglobulin therapy

- ◆ substitution
  - primary antibody immunodeficiency
  - secondary antibody immunodeficiency
- ◆ immunomodulation of autoimmune diseases
- ◆ 1 g approx.  $4 \times 10^{18}$  IgG molecules
- ◆ different dosing

# Mechanisms of IVIg effect

## - Fc fragment dependent

- blockade of Fc receptors on phagocytes (similar effect as MoAb anti-FcγR, lasts approx. 30 days)
- inhibition of proinflammatory cytokines by macrophages (in vitro)
- diminishing of NK cells function
- effect on Fc receptors on B cells (CD32)

# Mechanisms of IVIg effect

## - Fab fragment dependent

- different antigen neutralization
- anti-idiotypic activity
- inhibition of B cell differentiation and activation
- creation of rheumatoid factors (anti-Ig Ab)

# Clinical use of IVIg

## effect proven by RCT

- ◆ immune thrombocytopenia
- ◆ Guillain-Barré syndrome
- ◆ chronic demyelinating neuropathy
- ◆ Kawasaki disease
- ◆ Dermatomyositis
- ◆ Lambert-Eaton myasthenic syndrome
- ◆ Multifocal neuropathy

## effect not proven by RCT

- ◆ viral induced malaise
- ◆ rheumatoid arthritis
- ◆ juvenile rheumatoid arthritis

# Monoclonal antibodies in anti-cancer therapy

- ◆ conjugate of MoAb and cytotoxic drug (methotrexate, vinkristine), toxins (ricin, abrin), radioisotope (iod-131, yttrium-90)
- ◆ immunolocalization of tumour – radioisotope-labeled MoAb (indium-111, technecium-99)

# FDA approved MoAb in cancer

**Table 2.** Monoclonal Antibody Products

Name	Type	Target	Clinical
Rituximab	Chimeric	CD20	NHL
Trastuzumab	Humanized	Erb B2	Breast
Bevacizumab	Humanized	VEGF	Colorectal
Alemtuzumab	Humanized	CD52	CLL
Cetuximab	Chimeric	EGFR	Colorectal
Panitumumab	Human	EGFR	Colorectal

Abbreviations: NHL, non-Hodgkin's lymphoma; VEGF, vascular endothelial growth factor; CLL, chronic lymphocytic leukemia; EGFR, epidermal growth factor receptor.

# Immunostimulation by cytokines

## ◆ IFN alpha

- malignancy, hepatitis B and C
- flu-like symptoms, malaise, anorexy, mood changes, bone marrow suppression, hepatotoxicity, cardiotoxicity

## ◆ IFN beta

- multiple sclerosis
- possible effect due to inhibition of expression of HLA-DR on glial cells

## ◆ IFN gamma

- lepromatous lepra, leishmaniasis, chronic granulomatosis

## ◆ IL-2

- PID, HIV, increases number of CD4+ T cells

## ◆ GM-CSF, G-CSF

- production of new granulocytes, monocytes and macrophages

# Immunomodulation with antigen

1. immunotherapy of allergic diseases – use of defined exoallergen
2. cancer immunotherapy – DC, T cells
3. adoptive immunotherapy
4. immunotherapy of autoimmune diseases – hypothetical use of defined autoantigen

# Allergen-specific immunotherapy

- ◆ hyposensitization – repeated application of gradually growing doses of allergen
- ◆ lasts for 3-5 years
- ◆ isotype switch, degranulation of mast cells
- ◆ subcutaneous, inhalation, ingestion

# Allergy – sensitization and memory

# Immediate phase of allergic inflammation

# Late phase of allergic inflammation

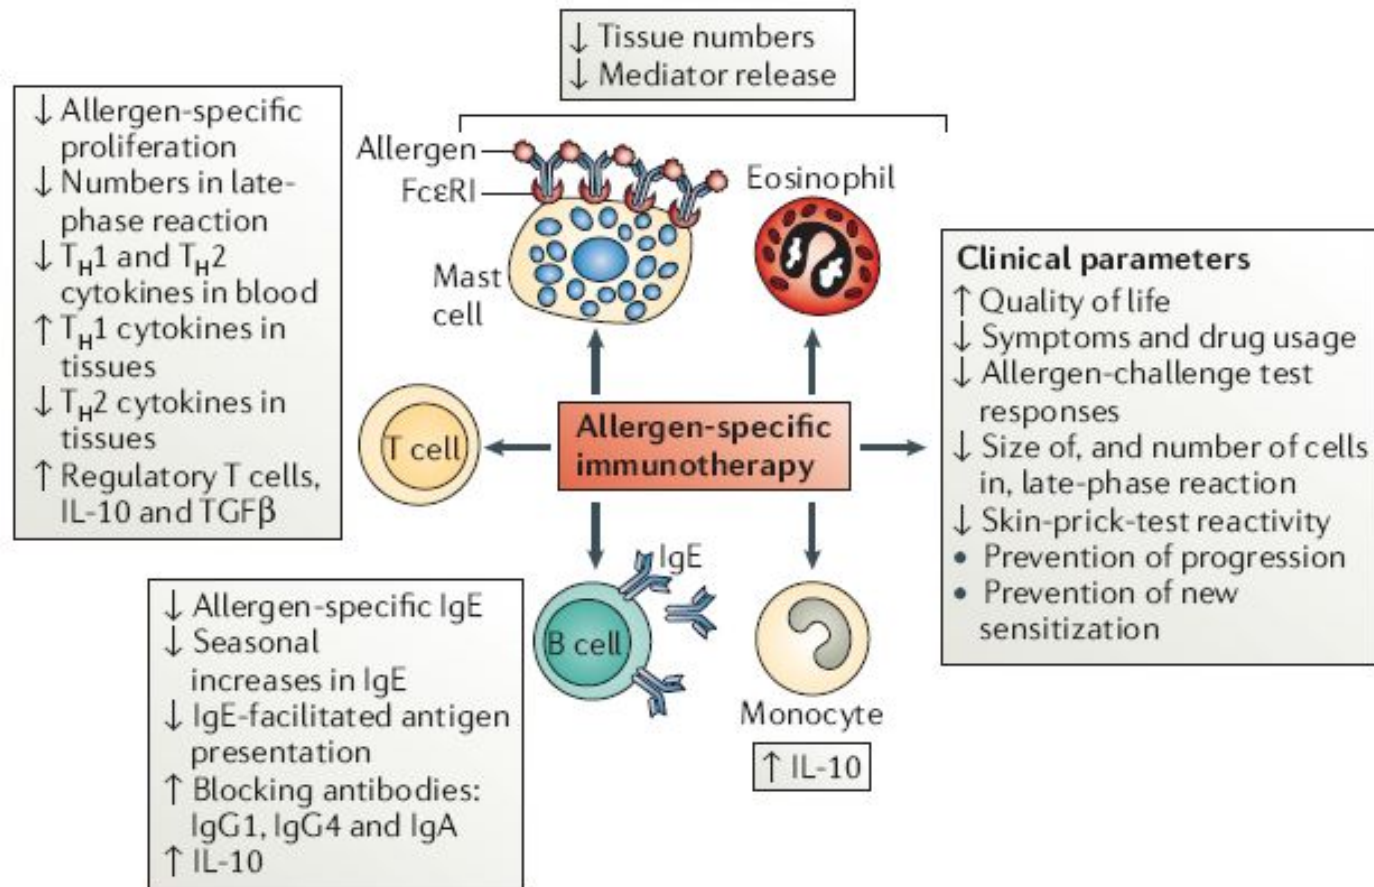

c La

# Proposed role of regulatory T cells in IT

# Effects of allergen-specific IT

# Dendritic cells based vaccines

- ◆ TLR receptors (Toll-like) – essential for the initiation of immune response
- ◆ If no TLR costimulation – Tcell anergy, expansion of regulatory T cells
- ◆ minimal residual disease
- ◆ need for costimulation
- ◆ inadequate activation
- ◆ role of tumour environment

# DC vaccines in anti-cancer IT

# Different DC loading techniques

DC loading technique	Advantages	Disadvantages
DCs loaded with defined tumour antigens	<ul style="list-style-type: none"> <li>• Induces CTL responses against leukaemia cells alone, not stem cells</li> </ul>	<ul style="list-style-type: none"> <li>• Antigen drift/loss</li> <li>• HLA restriction (for LAA-derived peptides)</li> <li>• Differing responses/avidity of CTLs to peptides</li> <li>• T-cell exhaustion if peptide already strongly expressed</li> </ul>
DCs loaded with undefined tumour antigens	<ul style="list-style-type: none"> <li>• Broad range of tumour antigens expressed including undefined antigens</li> <li>• Less likely for antigen drift to be relevant</li> </ul>	<ul style="list-style-type: none"> <li>• Difficult to induce pure apoptosis or necrosis — overlap in stages of cell death</li> <li>• May stimulate tolerogenic DCs/ danger signals</li> <li>• Broad range of antigens may induce autoimmunity</li> </ul>
AML-DCs/fusion hybrids	<ul style="list-style-type: none"> <li>• Combines features of both leukaemic cells and DCs</li> <li>• Broad range of tumour antigens expressed including unknown antigens</li> <li>• Less likely for antigen drift to be relevant</li> </ul>	<ul style="list-style-type: none"> <li>• Low conversion efficiency</li> <li>• Broad range of antigens may induce autoimmunity</li> </ul>

CTL, cytotoxic T lymphocyte; AML, acute myeloid leukaemia; HLA, human leukocyte antigen; LAA, leukaemia-associated antigen.

# Sites of action DC IT in cancer

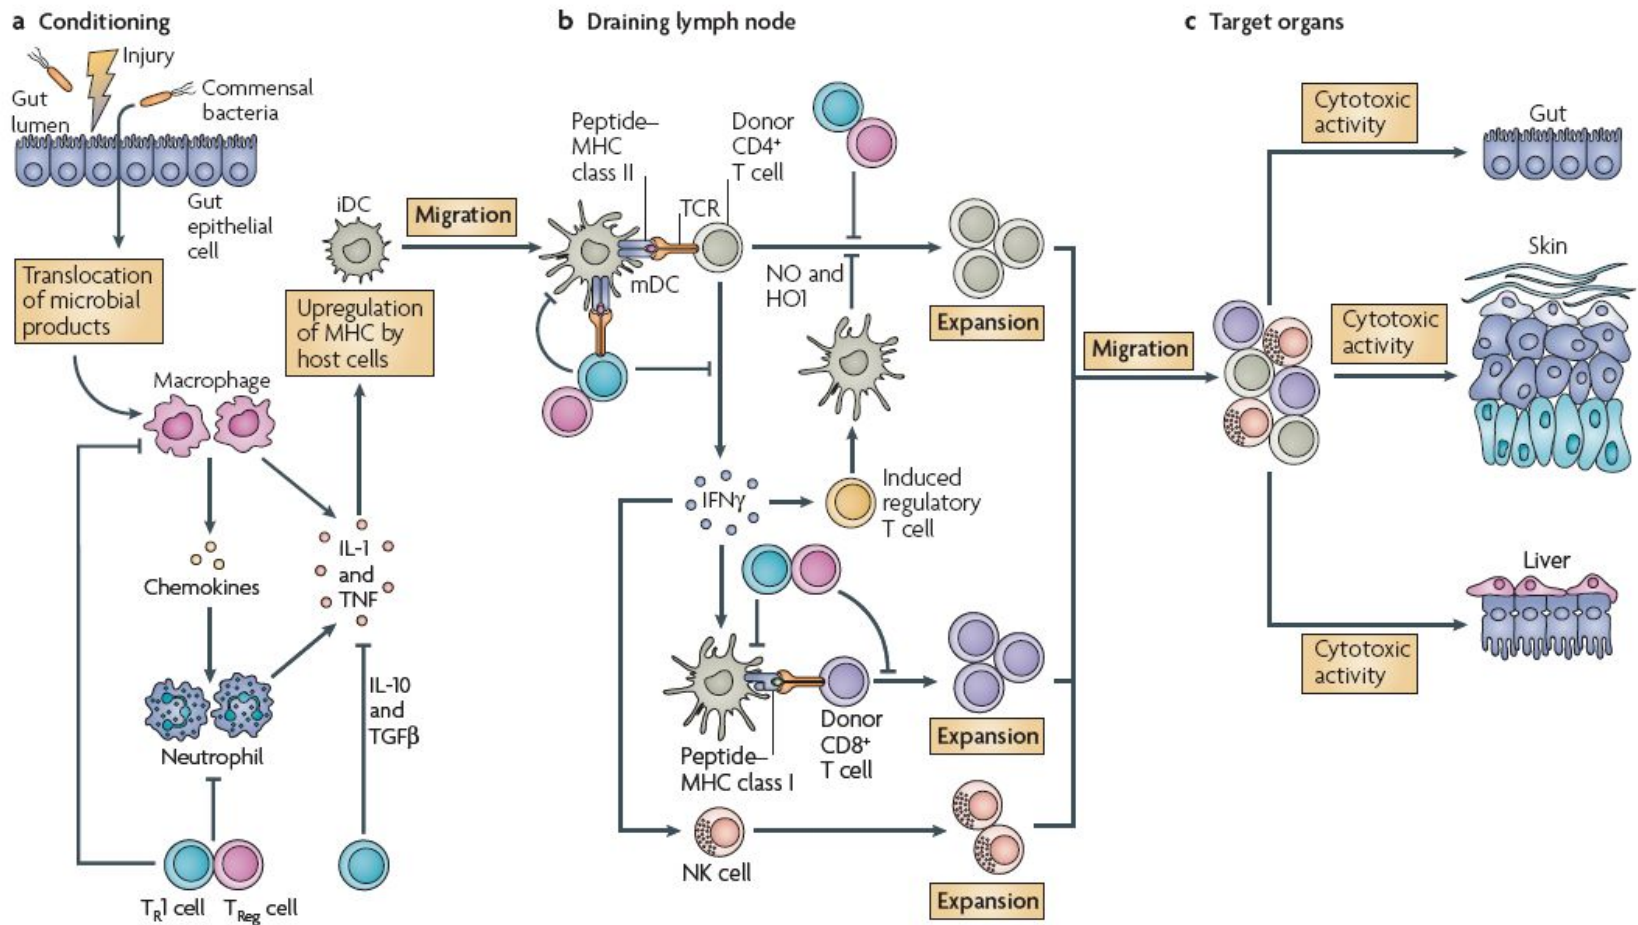

# Adoptive cell therapy in cancer

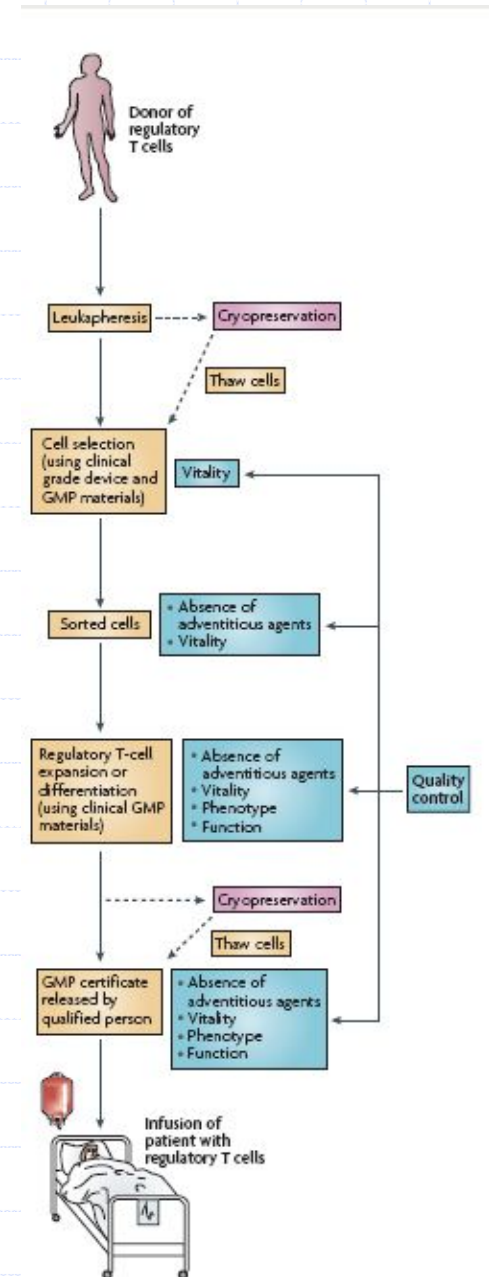

# Tregs in GvHD

# Clinical use of Tregs

diabetes

Rocarolo, Nat Rev Immunol, 2007

# Hematopoietic stem cell transplantation

- ◆ inborn errors
- ◆ mega-chemotherapy leading to BM ablation
- ◆ GvL effect
- ◆ autoimmune diseases
- ◆ first HSCT and first gene therapy – in PID

# Hematopoietic stem cell transplantation in immunodeficiency

# Gene therapy

- ◆ selective growth advantage
- ◆ ADA (no use of PEG-ADA), SCID
- ◆ site of integration may influence cell's fate
- ◆ proto-oncogene LMO2

# Gene therapy – viral vectors

**A** Retroviral vector used for the SCID clinical trials

**B** Self-inactivated vectors

**C** Self-inactivated vector containing 2 x (250 bp) cHS4 insulators

**D** Self-inactivated vector containing insulator and a suicide gene (TK)

**Figure 2**

Schematic representation of retroviral vectors and their modifications to improve safety. **(A)** The transcription of the therapeutic gene is driven by the enhancer-promoter activity of the U<sub>3</sub> region of the retroviral LTR. **(B)** The transcription of the therapeutic gene is driven by the addition of an internal promoter. The U<sub>3</sub> region of the retroviral LTR has been almost completely deleted. **(C)** The provirus contains the cHS4 element (i.e., insulator) in order to protect the transcriptional cassette against position effects. **(D)** This provirus contains 2 cassettes: (a) the therapeutic gene driven by a first internal promoter and (b) a suicide gene (e.g., thymidine kinase, *TK*) that could allow the elimination of gene-corrected cells if an adverse event such as a monoclonal proliferation occurs. EF-1a, elongation factor-1a; IRES, internal ribosome entry site; PGK, phosphoglycerate kinase; R, repeats; SA, site acceptor; SD, site donor.

# Gene therapy – homologous recombination

# Gene therapy - problems

- ◆ low effectivity of gene transfer
- ◆ low expression of the target protein
- ◆ mutagenesis - oncogenesis
- ◆ immunogenicity of the gene/vector

# Future of immunotherapy

- ◆ antigen specific immunosuppression
- ◆ lower toxicity and side effects
- ◆ the more we know about etiology, the more focused could be the attack

# Psychological aspects

- ◆ beta-endorphins
- ◆ during exams
  - lymphopenia
  - ↓ activity of NK cells
  - ↓ production of IFN-gamma
